# Correlations between Carcass Traits and Mineral Concentrations in Angus Beef raised in Iowa

## **Abstract**

Beef is a nutritious food that is known to have high bioavailability for several minerals such as iron and zinc. Although beef is typically high in these nutrients, there is much animal-to-animal variation in mineral contents. The objective of this study is to report the relationship between traditional carcass traits and mineral concentrations within the longissimus dorsi.

### Introduction

Beef is a nutritious food that is known to have high bioavailability for several minerals such as iron and zinc. Although beef is typically high in these nutrients, there is much animal-to-animal variation in mineral contents. The objective of this study is to report the relationship between traditional carcass traits and mineral concentrations within the *longissimus dorsi*.

### Materials and Methods

**Cattle Resource.** This project utilized 1,085 bulls (n = 540), steers (n = 236), and heifers (n = 309) born from spring 2002 to spring 2008 in the Iowa State University Angus Selection project as part of our research to investigate the genetic control of healthfulness of beef. These cattle came from 25 contemporary groups (with contemporary group defined as gender within harvest date). Contemporary group size ranged from 12 to 67, with an average size of 43.4. These cattle had carcass traits collected: hot carcass weight (HCW) (n = 1,085); 12<sup>th</sup> rib subcutaneous fat thickness (12<sup>th</sup> Fat) (n = 1,085); 12<sup>th</sup> rib longissimus dorsi area (12<sup>th</sup> REA) (n = 1,085); estimated percent kidney, pelvic, and heart fat (KPH) (n = 1,085); calculated yield grade (YG) (n = 1,085); marbling score (MARB) (n = 1,084); ether extracted fat (% Fat)

(n = 1,050); ultimate (approx. 48 hours post mortem) pH (UltpH) (n = 598); and Warner-Bratzler shear force (WBS) (n = 1,061). Concentrations of minerals {calcium (n = 1,077), copper (n = 986), magnesium (n = 1,079), manganese (n = 982), phosphorus (n = 1,079), potassium (n = 1,068), sodium (n = 1,079), zinc (n = 1,075), total iron (n = 1,072), nonheme iron (n = 980), heme iron (n = 980), and proportion of heme iron (n = 980)} in *longissimus dorsi* were evaluated.

**Statistical Analysis.** Correlations between carcass traits and mineral concentrations were initially calculated by using actual data (Table 1). However, we know that the gender and management of animals can systematically affect carcass traits (e.g., MARB and 12<sup>th</sup> Fat are lower in bulls than in steers and heifers). Therefore, we also calculated the deviation of each of these traits from their contemporary group means. The correlations between the deviations from contemporary group means were also calculated (Table 2).

### Results and Discussion

The relationships between phenotypes of traits seem to have been influenced by the grouping of animals in harvest date and gender groups. Table 1 shows that the raw correlation data of 54.6 percent (59/108) of the correlations were significantly different from zero ( $P < 0.05$ ). However, when the measures are deviated from their contemporary group mean and then the correlation analysis performed, only 39.8 percent (43/108) of the correlations are significantly different from zero ( $P < 0.05$ ). Carcass traits, which had the largest change in number of significant correlations between analysis methods, were fat related traits. For

minerals, manganese and zinc had the largest change in number of significant correlations between the analysis methods.

Overall, the correlations between economically important carcass traits and concentrations of health associated minerals are low ( $< \pm 0.30$ ). This correlation analysis indicates that selection or management for

manipulating carcass traits would likely have little effect on mineral concentrations.
